IR Analyzer Fault Lights

The LED labeled Fault is used as a diagnostic light, and under normal operation will flash dimly at rate of approximately 120 times per minute. When a fault condition exists the LED will flash at the rate of 1 per second with a significant increase in brightness.

Due to the variation in the light output from manufacturer production batches the diagnostic flashing (120 times per minute) in some instances is clearly visible this is an indication that the analyzer is functioning correctly.

Fault conditions are indicted by the Fault LED flashing at the rate of 1 per second at full brightness, in addition to the flashing LED the LCD screen will display Err.
